### ABSTRACT

**Background:** Tuberculosis (TB) is one of the most prevalent cause of death due to a single pathogen. Bacillus Calmette Guérin (BCG) is the only vaccine available for clinical use that protects against miliary TB; however, this vaccine has shown variable levels of efficacy against pulmonary TB. In Sudan, a single dose of BCG vaccine is given. The incidence of TB in Sudan is very high in spite of primary vaccination in neonatal period and therefore requires consideration for repeated immunization. **Objective:** To investigate the effect of BCG immunization in Mice challenged with *M. tuberculosis*. **Materials and Methods:** A total number of 160 mice were examined for their immunopotency and protective efficacy of BCG against challenge dose of *M. tuberculosis* as single dose. In experiment contains two groups of

mice each of ten mice  $n = 10$  (20mice). The first group(A) were immunized with BCG (0.2ml) first dose (I.P) for 21 days. The second group(B) were not immunized with BCG. All mice with BCG were tested for tuberculin skin test (TST) so as to determine susceptibility and resistance against tuberculosis. All the groups were challenged with (0.5ml) virulent *M. tuberculosis* H37Rv strain (American Type Culture Collection, ATCC 35718). *M. tuberculosis*.  $10^7$ (CFU). Another group of mice  $n=6$  for the study of humoral response by immunization of mice with immune serum and challenged with *M. tuberculosis* Following by two groups of mice  $n=10$  for each group A and B for the susceptibility and resistance of the strains of mice by immunization of mice with BCG for 21 days and testing by tuberculin skin test (TST). The efficacy was based on a survival rate of challenged mice, mortality rate and

bacterial load of *M. tuberculosis* in the lungs of infected mice. **Result:** After three weeks of observations Tuberculin skin test reaction for the BCG immunized mice were positive, hence the mice strain of BALB/c were susceptible and Swiss white mice were resistant for BCG. Survival mice in group (A) were 50%, and group(B) 0%.The mortality rates for (A) 50%, and (B) 100%. The immunopotency and protective efficacy of BCG first dose was (50%). Humoral immunity response against *M. tuberculosis* showed negative reaction hence mortality rate was 100%. **Conclusions:** The incidence of TB is high in spite of primary vaccination in neonatal period and therefore requires consideration for repeated immunization of BCG.

**KEYWORDS:** BCG, *M. tuberculosis*, BALB/c Mice, Swiss white mice, tuberculin skin test (TST).

## 1. INTRODUCTION

Tuberculosis (TB) is primarily a chronic lung infection that is one of the most potent and wide-spread human infections today, and a major cause of death from bacterial pathogens<sup>[1]</sup> It affects more young adults and therefore has a high impact on the socioeconomic status of people<sup>[2]</sup> In Africa, investigations of TB is complicated by the parallel epidemic of HIV because co-infection is common. This makes it necessary to consider HIV infection, especially in high HIV prevalent areas.<sup>[3]</sup> In 2015 an estimated 10.4 million new (incident) TB cases worldwide, of which 5.9 million (56%) were among men, 3.5 million (34%) among women and 1.0 million (10%) among children.<sup>[4]</sup> The BCG vaccine can provide effective protection against TB in up to 8 out of 10 people who are given it. Currently, BCG vaccinations are only recommended for groups of people who are at a higher risk of developing TB. in this context, *M. bovis* BCG is the only vaccine available for the prevention of tuberculosis in humans. The live, attenuated BCG vaccine, originally derived by serial passage of a virulent strain of *M. bovis*, has been used to prevent tuberculosis since 1921. The BCG is effective against severe forms of childhood tuberculosis but appears to be of limited efficacy against adult pulmonary disease in endemic areas.<sup>[5]</sup>

BCG vaccination includes children living in areas with high rates of TB, or those who have close family members from countries with high TB rates, and people under the age of 16 who are going to live and work with local people in an area with high rates of TB for more than three months. It's also recommended that some people, such as health care workers, are vaccinated because of the increased risk of contracting TB while working.<sup>[5]</sup> *Mycobacterium*

*bovis* based Bacille Calmette Guerin (BCG) was originally used as an oral vaccine in the 1930s. The movement from oral administration to intradermal injection began in the 1960s. *M. Bovis* originally infects the gastrointestinal tract of cattle and humans naturally. The BCG based vaccine can provide stimulation of both innate and acquired immunity.<sup>[5]</sup> Despite early success, the BCG vaccine has had a limited effect against the incidence of TB in the developing world. Various clinical trials have demonstrated that BCG showed variable levels of efficacy against pulmonary TB. For example, a major trial in the United Kingdom showed >75% protection.<sup>[6]</sup> However, trials in south India and Malawi demonstrated that BCG failed to protect consistently against pulmonary.<sup>[7]</sup> The reasons for this have been a matter of debate and this indicates an urgent need for more effective vaccines to decrease the incidence of tuberculosis.<sup>[6]</sup>

## 2. MATERIALS AND METHODS

### 2.1. Ethical consideration

All animals were housed and maintained in accordance with protocols approved by the Institutional Animal Care.

### 2.2. Animals

Inbred BALB/c mice were obtained from Veterinary research Laboratories (Khartoum, Sudan). The mice were maintained under pathogen-free conditions and used at 8–12 wk of age and out bred Pathogen-free Swiss mice (male 20-25 grams were also obtained from professor Hamid Suleiman (Parasitologist) Khartoum- Sudan. The mice were maintained in standard cages under sterile conditions and were fed commercial mice chow and water. All animals were housed and maintained in accordance with protocols approved by the Institutional Animal Care.

### 2.3. Bacteria and mice infections and immunizations

Virulent *M. tuberculosis* H37Rv strain (American Type Culture collection) and *M. bovis* BCG (Bacille Calmette – Guerin) Collection strain 1011).

### 2.4. Study design

This experimental study is going to be conducted with the transfer factor as immunotherapy in experimental pulmonary tuberculosis using laboratory animal that is mice which is going to be infected intraperitoneally (i.p.) with a 10 fold dilution of BCG. All procedures performed in a laminar flow cabinet in a biosafety facility.

### 2.5. Period of the study

The experiment is going to be conducted during the period September 2016 up to May 2017.

### 2.6. Collection of Samples

The slant culture of *Mycobacterium tuberculosis* obtained from L. J. medium which inoculated with the sputum of pulmonary TB. Patient, and inoculum obtained from the culture injected into mice. Infected mice maintained in cages in a laminar flow cabinet in a biosafety facility.

### 2.7. Sample size

In this experimental study a total number of 160 mice were used according to the equation of sample size for single-group experiments, in which  $n=10$  for the group of mice.

### 2.8. Inclusion criteria

Inbred BALB/c mice were included in this study for their susceptibility to BCG immunization.

### 2.9. Exclusion criteria

Swiss white out bred mice were excluded for their resistant to BCG.

### 2.10. Procedure

A total number of 160 mice were examined for their immunopotency and protective efficacy of BCG against challenge dose of *M. tuberculosis* as single dose. In experiment contains two groups of inbred BALB/c male mice of 6-8 weeks of age, weighing 25-30 grams mice each of ten mice  $n = 10$  (20 mice). The first group(A) were immunized with (0.5ml) of BCG which diluted with 10ml of normal saline in sterile container in ice for 21days as first dose (I.P) for 21 days. The second group(B) were not immunized with BCG. All mice with BCG were tested for tuberculin skin test (TST) so as to determine susceptibility and resistance against tuberculosis.

### 2.11. Tuberculin skin Test procedure (20 mice)

Intradermal injection of mice with 0.2 ml of purified protein derivative (PPD) and then induration and swelling were observed in the skin of tested mice after 24-72 hours. All the three groups were challenged with (0.5ml) virulent *M. tuberculosis* H37Rv strain (American Type Culture Collection, ATCC 35718) *M. tuberculosis*. $10^7$ (CFU).

### 2.12. Challenge dose

Preparation of different concentration of *M. tuberculosis* by McFarland 0.5 and colony forming unit (CFU) of  $10^2, 10^3, 10^4$ , up to  $10^9$ . McFarland standards were made by mixing specified amounts of Barium chloride and Sulfuric acid together. Mixing the two compounds forms a Barium Sulfate precipitate, which causes turbidity in the solution. A 0.5 McFarland standard is prepared by mixing 0.05 ml of 1.175% barium chloride dihydrate ( $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$ ), with 9.95 ml of 1% sulfuric acid ( $\text{H}_2\text{SO}_4$ ). The standard was compared visually to a suspension of bacteria in sterile saline or nutrient broth. If the bacterial suspension was too turbid, it was then diluted with more saline. If the suspension was not turbid enough, more bacteria was added.

### 2.13. Preparation of inoculum for LD<sub>50</sub> determination of *M. tuberculosis* (100 mice)

On the day of inoculation the optical density (O.D.<sub>540nm</sub>) of bacterial suspension of *M. tuberculosis* was adjusted to 1.35 and 1ml of suspension then serial dilutions ( $10^0, 10^1, 10^2, 10^3, 10^4$ , up to  $10^9$ ) were prepared in saline, for each dilution 6 mice of each group were inoculated with 0.5ml intraperitoneally. Inoculation of 0.5 ml of different concentrations  $10^2, 10^3, 10^4$ , up to  $10^9$  of *M. tuberculosis*. McFarland 0.5 intraperitoneally in a group of 6 mice for each concentration to determine the LD<sub>50</sub>. The concentration of the suspensions which kills 50% of the mice is the LD<sub>50</sub>. The control group received normal saline 0.5ml intraperitoneally. Observations of the two groups were done for one week after the inoculation of different concentrations of *M. tuberculosis* and the normal saline were recorded. Lethal dose (LD<sub>50</sub>) concentration which kills 50% of the mice was recorded. Another group of mice n=10 for the study of humoral response by immunization of mice with immune serum and challenged with *M. tuberculosis*. Following by two groups of mice n=10 for each group A and B for the susceptibility and resistance of the strains of mice by immunization of mice with BCG for 21 days and testing by tuberculin skin test (TST). The efficacy was based on a survival rate of challenged mice, mortality rate and bacterial load of *M. tuberculosis* in the lungs of infected mice.

### Statistical analysis

A total number of 160 mice were used, Experiment(1) contains two groups of mice each of ten mice n = 10 (20mice). The first group(A) were immunized with BCG first dose (I.P) for 21 days. The second group (B) were not immunized with BCG. All the two groups were challenged with virulent M.TB. After three weeks of observations the results were as

following. Survival mice in group (A) were 50%, group (B) 0%. Experiment(2) Preparation of inoculum for LD<sub>50</sub> determination of M.tb. Inoculation of 0.5 ml of different concentrations 10<sup>2</sup>, 10<sup>3</sup>, 10<sup>4</sup>, upto 10<sup>9</sup> of M.tb. McFarland 0.5 intraperitoneally in group of 10 mice for each concentration (100 mice) to determine the LD<sub>50</sub> from the results which mean the concentration of the suspensions which kills 50% of the mice. Experiment(3) contains two groups of mice each of ten mice n = 10 (20mice). Mice were tested for susceptibility and resistance first for BCG by tuberculin skin test and if showed positive reaction that mean they are susceptible for BCG and resistant for M.TB. and vice versa. Experiment(4) contains two groups of mice each of ten mice n = 10 (20mice). Mice were tested for Humoral response of mice against M.TB. compared with BCG. The result was death of the mouse within 24hours, and mortality rate was 100% compared with 50% BCG first dose.

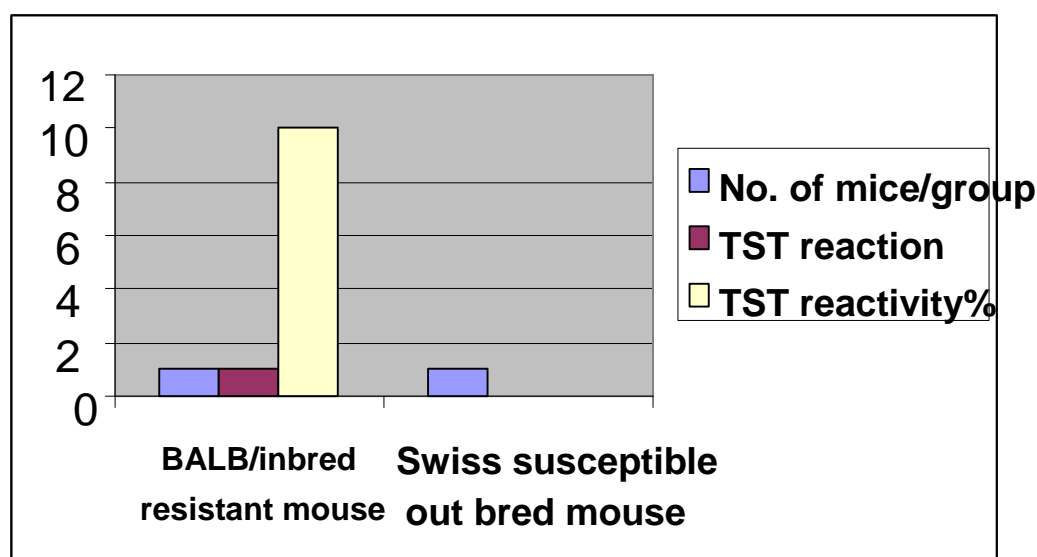

### 3. RESULTS

#### 3.1. Results of tuberculin skin test in BCG immunized mice

A total number of 20 inbred BALB/c mice and Swiss out bred were tested for tuberculin skin test (TST) BALB/c mice positive after immunization with BCG while out bred Swiss white mice were negative for TST.

**Table 1: The results of tuberculin skin test reaction (TST).**

Type of mouse strain	No. of mice/group	TST reaction
BALB/c inbred susceptible mouse	10	Positive
Swiss out bred resistant mouse	10	Negative

**Figure 1: The results of susceptibility and resistance of mice to *Mycobacterium tuberculosis*.**

TST reactivity%.: Mice were tested for susceptibility and resistance first for BCG by tuberculin skin test and if showed positive reaction that mean they are susceptible for BCG and resistant for M.TB. and vice versa.

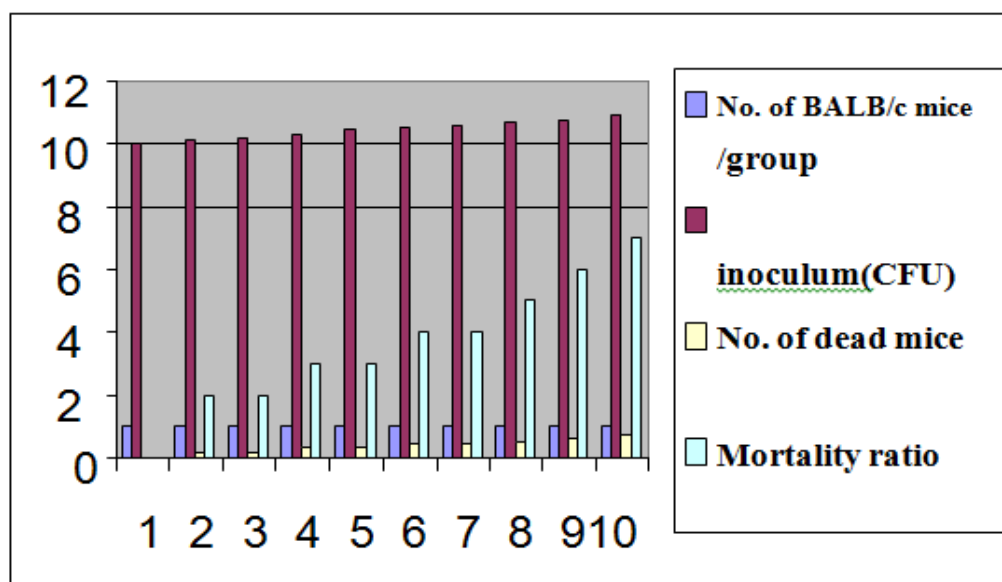

### 3.2. Results of LD<sub>50</sub> concentration

Figure (1) shows the groups mice inoculated with different concentrations of *M. tuberculosis*. ( $10^2, 10^3, 10^4$ , up to  $10^9$ ) and the normal saline (control group) for one week showed that the group of colony forming unit (CFU) ( $10^0$ ) exhibited no death of mice. Mice given ( $10^1$ ) and ( $10^2$ ) were exhibited 2 deaths out of 10 (2/10) i.e. mortality ratio 20%. The groups of ( $10^3$ ) and ( $10^4$ ) showed 3 deaths out of 10 (3/10) i.e. mortality ratio 30%. In the groups given ( $10^5$ ) and ( $10^6$ ) 4 deaths out of 10 (4/10), mice showed mortality ratio 40%, and CFU ( $10^7$ ) of mice showed 5 deaths out of 10 (5/10) with mortality ratio 50%. This showed that the lethal dose (LD<sub>50</sub>) which killed 50% of the total number of the mice.

**Table 2: Shows the results of LD<sub>50</sub> determination.**

No. of BALB/c mice /group	Bacterial inoculum(CFU)	No. of dead mice	Mortality ratio
10	$10^0$	0	0%
10	$10^1$	2	20%
10	$10^2$	2	20%
10	$10^3$	3	30%
10	$10^4$	3	30%
10	$10^5$	4	40%
10	$10^6$	4	40%
10	$10^7$	5	50%
10	$10^8$	6	60%
10	$10^9$	7	70%

**Figure 2:** The results of LD<sub>50</sub>inoculum(CFU) concentration which killed 50% of mice was 10<sup>7</sup> CFU in which five out of ten (5/10) that was 50% were died and the remaining 50% survived.

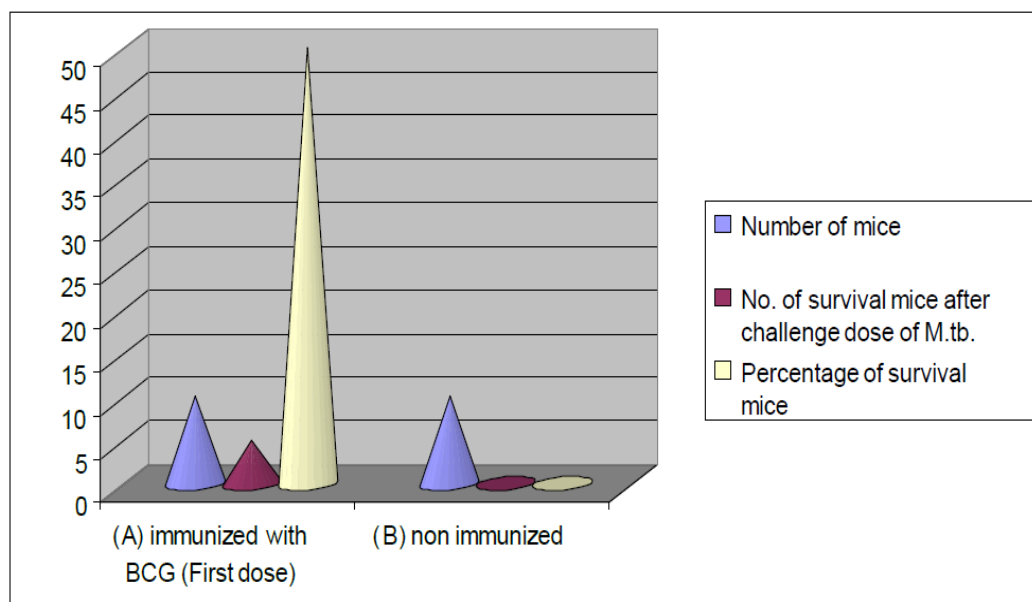

### 3.3. Results of vaccination with single dose of BCG in mice

Survival mice in group (A) were 50%, and group(B) 0%.The mortality rates for (A) 50% and (B) 100%. The immunopotency and protective efficacy of BCG first dose was (50%) and mortality rates of BCG first dose was(50%).For Group (B) which were not immunized 100% mortality and 0% protective efficacy after challenge dose of *M. tuberculosis*.

**Table (3):** The results of single BCG vaccination in mice.

Group of mice	Number of mice/group	No. of survival mice after challenge dose of M.tb.	No. of dead mice	Protective efficacy%	Mortality rate%
(A) immunized with BCG (First dose)	10	5	5	50%	50%
(B)only challenge dose of M.tb.)	10	0	10	0%	100%

**Figure(3) The results of immunopotency of BCG in mice (survival rate of challenged mice).**

**3.5. The results of Humoral response of mice against *Mycobacterium tuberculosis*.** The result was death of the mice within 24hours, and mortality rate of humoral response of mice against *Mycobacterium tuberculosis* was 100% compared with 50% BCG first dose.

**Table (4): The results of Humoral response of mice against *Mycobacterium tuberculosis*.**

Group of mice	Mortality rate%
(A) immunized with BCG (First dose)	50
(B) Serum of BCG immunized mouse	100

#### 4. DISCUSSION

In this current study a single dose of BCG vaccination intraperitoneally (i.p) was used in BALB/c mice which were free of pathogen for a period of 21days to evaluate the efficacy of BCG. Vaccination measured by Delayed type hypersensitivity (DTH), survival of challenged mice and bacterial load in the infected lungs of mice. In this current study challenged mice which were found that the survival rate was 50% of BCG single dose. In this current study confirmed that BALB/c mice has a positive tuberculin skin test response compared to outbred Swiss mice, indicating that the delayed-type hypersensitivity (DTH) to *M. tuberculosis* antigens is diminished. In this current study BCG vaccination measured through survival of challenged mice and DTH. The efficacy of BCG against challenge dose of *M. tuberculosis* was 50% and mortality rate was 50% The obtained results are similar to previous studies

done by Turner; *et al* in 2001.<sup>[8]</sup> Who demonstrated used low-dose aerosol infection of *M. tuberculosis* to compare chronic tuberculosis. Susceptible mice, which are often able to contain bacterial growth in the liver and spleen, are unable to restrict growth in the lung. While granulomas in resistant mice are well organized, consisting of aggregated lymphocytes and macrophages, lesions in susceptible mice are often poorly organized, necrotic and contain few lymphocytes. This implies that susceptible strains have a defect in recruiting or retaining lymphocytes in the lung. The production of cytokines crucial for the control of tuberculosis, such as IFN $\gamma$ , is usually diminished in susceptible mice, resulting in a general delay in the effect or phase of the adaptive immune response. In many cases, susceptible mice are deficient in maintaining a single dose.<sup>[9]</sup>

## 5. CONCLUSION

Inbred strains of mice exhibit varied patterns of susceptibility following infection with virulent *M. tuberculosis*. Susceptible mice have progressive fulminate disease resulting in their premature death; in contrast, resistant mice are able to control bacterial replication, limit lung injury and survive longer.
